PART I. SLIDE RULE OPERATION

INTRODUCTION

The slide rule is a fairly simple tool by means of which answers to involved mathematical problems can be easily obtained. To solve problems easily and with confidence it is necessary to have a clear understanding of the operation of your slide rule. Speed and accuracy will soon reward the user who makes a careful study of the scale arrangements and the manual.

The slide rule consists of three parts: (1) the stator (upper and lower bars); (2) the slide; (3) the cursor or indicator. The scales on the bars and slide are arranged to work together in solving problems. The hairline on the indicator is used to help the eyes in reading the scales and in adjusting the slide.

Each scale is named by a letter (A, B, C, D, L, S, T) or other symbol at the left end.

The table below shows some of the mathematical operations which can be done easily and quickly with an ordinary slide rule.

<table>
<thead>
<tr>
<th>OPERATIONS</th>
<th>INVERSE OPERATIONS</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multiplying two or more numbers</td>
<td>Dividing one number by another</td>
</tr>
<tr>
<td>Squaring a number</td>
<td>Finding the square root of a number</td>
</tr>
<tr>

<td>Finding a number whose logarithm is known</td>
</tr>
<tr>
<td>Finding the sine, cosine, or tangent of an angle</td>
<td>Finding an angle whose sine, cosine, or tangent is known</td>
</tr>
</tbody>
</table>

Various combinations of these operations (such as multiplying two numbers and then finding the square root of the result) are also easily done. Numbers can be added or subtracted with an ordinary slide rule, but it is usually easier to do these operations by arithmetic.*

In order to use a slide rule, a computer must know: (1) how to read the scales; (2) how to "set" the slide and indicator for each operation to be done; and (3) how to determine the decimal point in the result.

*By putting special scales on a slide rule, these and certain other operations much more difficult than those shown in the table above can be done easily.
PREFACE

A computer who must make many difficult calculations usually has a book
of tables of the elementary mathematical functions, or a slide rule, close at hand.
In many cases the slide rule is a very convenient substitute for a book of tables.
It is, however, much more than that, because by means of a few simple adjust-
ments the actual calculations can be carried through and the result obtained.
One has only to learn to read the scales, how to move the slide and indicator,
and how to set them accurately, in order to be able to perform long and other-
wise difficult calculations.

When people have difficulty in learning to use a slide rule, usually it is not
because the instrument is difficult to use. The reason is likely to be that they
do not understand the mathematics on which the instrument is based, or the
formulas they are trying to evaluate. Some slide rule manuals contain relatively
extensive explanations of the theory underlying the operations. Some explain
in detail how to solve many different types of problems — for example, various
cases which arise in solving triangles by trigonometry. In this manual such
theory has deliberately been kept to a minimum. It is assumed that the theory
of exponentials, of logarithms of trigonometry, and of the slide rule is known to
the reader, or will be recalled or studied by reference to formal textbooks on
these subjects. This is a brief manual on operational technique and is not inten-
ted to be a textbook or workbook. Relatively few exercises are included,
and the answers of these (to slide rule accuracy) are given immediately so that
learning may proceed rapidly, by self-correction if necessary. Any textbook on
mathematics which contains problems suitable for slide rule calculation, and
their answers, will provide additional practice.

PART 4 — CONVERSION TRIG SLIDE RULE          | 39   |
HOW TO READ THE SCALES

The scale labeled C (on the slide) and the scale D (on the stator bar) are used most frequently. These two scales are exactly alike. The total length of these scales has been separated into many smaller parts by fine lines called "graduations."

Some of these lines on the D scale have large numerals (1, 2, 3, etc.) printed just below them. These lines are called primary graduations. On the C scale the numerals are printed above the corresponding graduations. A line labeled 1 at the left end is called the left index. A line labeled 1 at the right end is called the right index.

Fig. 2

Next notice that the distance between 1 and 2 on the D scale has been separated into 10 parts by shorter graduation lines. These are the secondary graduations. (On 10 inch slide rules these lines are labeled with smaller numerals 1, 2, 3, etc. On 6 inch rules these lines are not labeled.) Each of the spaces between the larger numerals 2 and 3, between 3 and 4, and between the other primary graduations is also sub-divided into 10 parts. Numerals are not printed beside these smaller secondary graduations because it would crowd the numerals too much.

Fig. 3

When a number is to be located on the D scale, the first digit is located by use of the primary graduations. The second digit is located by use of the secondary graduations. Thus when the number 17 is located, the 1 at the left index represents the 1 in 17. The 7th secondary graduation represents the 7. When 54 is to be located, look first for primary graduation 5, and then for secondary graduation 4 in the space immediately to the right.

There are further sub-divisions, or tertiary graduations, on all slide rules. The meaning of these graduations is slightly different at different parts of the scale. It is also different on a 6 inch slide rule than on a 10 inch rule. For this reason a separate explanation must be given for each.

Fig. 4

Tertiary graduations on 10 inch rules.

The space between each secondary graduation at the left end of the rule (over to primary graduation 2) is separated into ten parts, but these shortest graduation marks are not numbered. In the middle part of the rule, between the primary graduations 2 and 4, the smaller spaces between the secondary graduations are separated into five parts. Finally, the still smaller spaces between the secondary graduations at the right of 4 are separated into only two parts.

To find 173 on the D scale, look for primary division 1 (the left index), then for secondary division 7 (numbered) then for smaller subdivision 3 (not numbered, but found as the 3rd very short graduation to the right of the longer graduation for 7).

Fig. 5

Similarly, 149 is found as the 9th small graduation mark to the right of the 4th secondary graduation mark to the right of primary graduation 1.

To find 246, look for primary graduation 2, then for the 4th secondary graduation after it (the 4th long line), then for the 3rd small graduation after it. The smallest spaces in this part of the scale are sixtieths. Since \( \frac{3}{6} = \frac{1}{20} \), then the third graduation, marking three sixtieths, is at the same point as six tenths would be.

Tertiary graduations on 6 inch rules.

The space between each secondary graduation at the left end of the rule (over to primary graduation 2) is separated into five parts. In the middle of the rule, between the primary graduations 2 and 5, the smaller spaces between the secondary graduations are separated into two parts. Finally, the still smaller spaces between the secondary graduations at the right of 5 are not subdivided.

To find 172 on the D scale, look for the primary division 1 (the left index), then for the secondary division 6 which is the 7th secondary graduation.
To find 146, look for the primary graduation 1, then for the 4th secondary graduation after it (the 4th secondary line), then for the 3rd small graduation after it. The smallest spaces in this part of the scale are fifths. Since \( \frac{3}{5} = \frac{6}{10} \), then the third graduation, marking three fifths, is at the same point as six tenths would be.

The number 147 would be half of a small space beyond 146. With the aid of the hairline on the runner the position of this number can be located approximately by the eye. The small space is mentally “split” in half.

The number 385 is found by locating primary graduation 3 and then secondary graduation 8 (the 8th long graduation after 3). Following this, one observes that between secondary graduations 8 and 9 there is one short mark. Think of this as the “5 tenths” mark, which represents 385. The location of 383 can be found approximately by mentally “splitting” the space between 380 and 385 into fifths, and estimating where the 3rd “fifths” mark would be placed. It would be just a little to the right of halfway between 380 and 385.

On the scale below are some sample readings:

```
A: 195
B: 119
C: 110
D: 101
E: 223
F: 206
G: 465
H: 402
I: 694
J: 987
```

The symbols 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, used in writing numbers are called digits. One way to describe a number is to tell how many digits are used in writing it. Thus 54 is a "two-digit number", and 1,348,256 is a "seven-digit number." In many computations only the first two or three digits of a number need to be used to get an approximate result which is accurate enough for practical purposes. Usually not more than the first three digits of a number can be "set" on a six inch slide rule scale. In many practical problems this degree of accuracy is sufficient. When greater accuracy is desired, a ten inch slide rule is generally used.

### MULTIPLICATION

Numbers that are to be multiplied are called factors. The result is called the product. Thus, in the statement \( 6 \times 7 = 42 \), the numbers 6 and 7 are factors, and 42 is the product.

#### EXAMPLE: Multiply \( 2 \times 3 \)

**Setting the Scales:** Set the left index of the C scale on 2 of the D scale. Find 3 on the C scale, and below it read the product, 6, on the D scale.

**Think:** The length for 2 plus the length for 3 will be the length for the product.

This length, measured by the D scale, is 6.

#### Example: Multiply \( 4 \times 2 \)

**Setting the Scales:** Set the left index of the C scale on 4 of the D scale. Find 2 on the C scale, and below it read the product, 8, on the D scale.

**Think:** The length for 4 plus the length for 2 will be the length for the product.

This length, measured by the D scale, is 8.

**Rule for Multiplication:** Over one of the factors on the D scale, set the index of the C scale. Locate the other factor on the C scale, and directly below it read the product on the D scale.

#### Example: Multiply \( 2.34 \times 36.8 \)

**Estimate the result:** First note that the result will be roughly the same as \( 2 \times 40 \), or 80, that is, there will be two digits to the left of the decimal point. Hence, we can ignore the decimal points for the present and multiply as though the problem was \( 234 \times 368 \).

**Set the Scales:** Set the left index of the C scale on 234 of the D scale. Find 368 on the C scale and read product 861 on the D scale.

**Think:** The length for 234 plus the length for 368 will be the length for the product. This length is measured on the D scale. Since we already knew the result was somewhere near 80, the product must be 861.1, approximately.

#### Example: Multiply \( 28.3 \times 5.46 \)

Note first that the result will be about the same as \( 30 \times 5 \), or 150. Note also that if the left index of the C scale is set over 283 on the D scale, and 546 is then found on the C scale, the slide projects so far to the right of the rule that the D scale is no longer below the 546. When this happens, the other index of the C scale must be used. That is, set the right index on the C scale over 283 on the D scale. Find 546 on the C scale and below it read the product on the D scale. The product is 154.5.

These examples illustrate how in simple problems the decimal point can be placed by use of an estimate.

DIVISION

In mathematics, division is the opposite or inverse operation of multiplication. In using a slide rule this means that the process for multiplication is reversed. To help in understanding this statement, set the rule to multiply 2 \times 4 (see page 7). Notice the result 8 is found on the D scale under 4 of the C scale. Now to divide 8 by 4 these steps are reversed. First find 8 on the D scale, set 4 on the C scale over it, and read the result 2 on the D scale under the index of the C scale.

Think: From the length for 8 (on the D scale) subtract the length for 4 (on the C scale). The length for the difference, read on the D scale, is the result, or quotient.

With this same setting you can read the quotient of 6 \div 3, or 9 \div 4.5, and in fact all divisions of one number by another in which the result is 2.

Rule for Division: Set the divisor (on the C scale) opposite the number to be divided (on the D scale). Read the result, or quotient, on the D scale under the index of the C scale.

EXAMPLES:

(a) Find 63.4 \div 3.29. The quotient must be near 20, since 60 \div 3 = 20. Set indicator on 63.4 of the D scale. Move the slide until 3.29 of the C scale is under the hairline. Read the result 19.27 on the D scale at the C index.

(b) Find 26.4 \div 47.7. Since 26.4 is near 25, and 47.7 is near 50, the quotient must be roughly 25/50 = 1/2 = 0.5. Set 47.7 of C opposite 26.4 of D, using the indicator to aid the eyes. Read 0.535 on the D scale at the C index.

DECIMAL POINT LOCATION

In the discussion which follows, it will occasionally be necessary to refer to the number of "digits" and number of "zeros" in some given numbers.

When numbers are greater than 1 the number of digits to the left of the decimal point will be counted. Thus 734.05 will be said to have 3 digits. Although as written the number indicates accuracy to five digits, only three of these are at the left of the decimal point.

Numbers that are less than 1 may be written as decimal fractions. Thus .673, or six-hundred-seventy-three thousandths, is a decimal fraction. Another example is .000465. In this number three zeros are written to show where the decimal point is located. One way to describe such a number is to tell how many zeros are written to the right of the decimal point before the first non-zero digit occurs.

In scientific work a zero is often written to the left of the decimal point, as in 0.00541. This shows that the number in the units’ place is definitely 0, and that no digits have been carelessly omitted in writing or printing. The zeros will not be counted unless they are (a) at the right of the decimal point, (b) before or at the left of the first non-zero digit, and (c) are not between other digits. The number 0.000408 will be said to have 3 zeros (that is, the number of zeros between the decimal point and the 4).

In many, perhaps a majority, of the problems met in genuine applications of mathematics to practical affairs, the position of the decimal point in the result can be determined by what is sometimes called "common sense." There is usually only one place for the decimal point in which the answer is "reasonable" for the problem. Thus, if the calculated speed in miles per hour of a powerful new airplane comes out to be 4833, the decimal point clearly belongs between the 3’s, since 48 m.p.h. is too small, and 4833 m.p.h. is too large for such a plane. In some cases, however, the data are such that the position of the point in the final result is not easy to get by inspection.

Another commonly used method of locating the decimal point is by estimation or approximation. For example, when the slide rule is used to find 133.4 \times 12.4, the scale reading for the result is 1655, and the decimal point is to be determined. By rounding off the factors to 133.0 \times 10.0, one obtains 1330 by mental arithmetic. The result would be somewhat larger than this but certainly contains four digits on the left of the decimal point. The answer, therefore, must be 1655.

In scientific work numbers are often expressed in standard form. For example, 428 can be written 4.28 \times 10^2, and 0.00393 can be written as 3.93 \times 10^{-3}.

When a number is written in standard form it always has two factors. The first factor has one digit (not a zero) on the left of the decimal point, and usually other digits on the right of the decimal point. The other factor is a power of 10 which places the decimal point in its true position if the indicated multiplication is carried out. In many types of problems this method of writing numbers simplifies the calculation and the location of the decimal point.

*Only positive real numbers are being considered in this discussion.*
When a number is written in standard form, the exponent of 10 may be called "the characteristic." It is the characteristic of the logarithm of the number to base 10. The characteristic may be either a positive or a negative number. Although the rule below appears long, in actual practice it may be used with great ease.

**Rule.** To express a number in standard form:

(a) place a decimal point at the right of the first non-zero digit.*

(b) Start at the right of the first non-zero digit in the original number and count the digits and zeros passed over in reaching the decimal point. The result of the count is the numerical value of the characteristic, or exponent of 10. If the original decimal point is toward the right, the characteristic is positive (+). If the original decimal point is toward the left, the characteristic is negative (−). Indicate that the result of (a) is to be multiplied by 10 with the exponent thus determined in (b).

**EXAMPLES:**

<table>
<thead>
<tr>
<th>Number</th>
<th>Number in standard form</th>
<th>Characteristic</th>
</tr>
</thead>
<tbody>
<tr>
<td>(a) 5,790,000</td>
<td>5.79 × 10^6</td>
<td>6</td>
</tr>
<tr>
<td>(b) 0.000283</td>
<td>2.83 × 10^-4</td>
<td>−4</td>
</tr>
<tr>
<td>(c) 44</td>
<td>4.4 × 10^1</td>
<td>1</td>
</tr>
<tr>
<td>(d) 0.623</td>
<td>6.23 × 10^-1</td>
<td>−1</td>
</tr>
<tr>
<td>(e) 8.15</td>
<td>8.15 × 10^0</td>
<td>0</td>
</tr>
<tr>
<td>(f) 461,328</td>
<td>4.61328 × 10^5</td>
<td>5</td>
</tr>
<tr>
<td>(g) 0.0000003571</td>
<td>5.371 × 10^-7</td>
<td>−7</td>
</tr>
<tr>
<td>(h) 0.0306</td>
<td>3.06 × 10^-2</td>
<td>−2</td>
</tr>
<tr>
<td>(i) 80.07</td>
<td>8.007 × 10^1</td>
<td>1</td>
</tr>
</tbody>
</table>

If a number given in standard form is to be written in "ordinary" form, the digits should be copied, and then starting at the right of the first digit the number of places indicated by the exponent should be counted, supplying zeros as necessary, and the point put down. If the exponent is positive, the count is toward the right; if negative, the count is toward the left. This converse application of the rule may be verified by studying the examples given above.

Consider now the calculation of 5,790,000 × 0.000283. From examples (a) and (b) above, this can be written 5.79 × 10^6 × 2.83 × 10^-4, or by changing order and combining the exponents of 10, as 5.79 × 2.83 × 10^2. Then since 5.79 is near 6, and 2.83 is near 3, the product of these two factors is known to be near 18. The multiplication by use of the C and D scales shows it to be about 16.39, or 1.639 × 10^1. Hence, 5.79 × 2.83 × 10^2 = 1.639 × 10^1 = 1.639 × 10^1 = 16.39. If, however, one has

5,790,000 ÷ 0.000283, the use of standard form yields

\[ 5.79 \times 10^6 \times 2.04 \times 10^{-4} = 2.04 \times 10^{10} \]

In scientific work the result would be left in this form, but for popular consumption it would be written as 20,400,000,000. The general rule is as follows.

**Rule.** To determine the decimal point, first express the numbers in standard form. Carry out the indicated operations of multiplication or division, using the laws of exponents to combine the exponents until a single power of 10 is indicated. If desired, write out the resulting number, using the final exponent of 10 to determine how far, and in what direction, the decimal point in the coefficient should be moved.

**CONTINUED PRODUCTS**

Sometimes the product of three or more numbers must be found. These "continued" products are easy to get on the slide rule.

**EXAMPLE:** Multiply 38.2 × 1.65 × 8.9.

Estimate the result as follows: 40 × 1 × 10 = 400. The result should be, very roughly, 400.

**Setting the Scales:** Set left index of the C scale over 382 on the D scale. Find 165 on the C scale, and set the hairline on the indicator on it.** Move the index on the slide under the hairline. In this example, the left index is placed under the hairline, then 89 on the C scale falls outside the D scale. Therefore, move the right index under the hairline. Move the hairline to 89 on the C scale and read the result (361) under it on the D scale.

Below is a general rule for continued products: \( a \times b \times c \times d \times e \cdots \)

Set hairline of indicator at \( a \) on D scale.
Move index of C scale under hairline.
Move hairline over \( b \) on the C scale.
Move index of C scale under hairline.
Move hairline over \( c \) on the C scale.
Move index of C scale under hairline.

Continue moving hairline and index alternately until all numbers have been set.

Read result under the hairline on the D scale.

**PROBLEMS**

1. 2.9 × 3.4 × 7.5
2. 17.3 × 13 × 9.2
3. 3.43 × 0.15 × 0.0032
4. 19 × 407 × 0.0021
5. 13.5 × 709 × 0.567 × 0.97

**COMBINED MULTIPLICATION AND DIVISION**

Many problems call for both multiplication and division.

**EXAMPLE:**

\[ \frac{12 \times 37}{65} \]

*See any textbook on elementary algebra. The theory of exponents and the rules of operation with signed numbers are both involved in a complete treatment of this topic. In this manual it is assumed that the reader is familiar with these topics.

**The product of 382 × 165 could now be read under the hairline on D scale, but this is not necessary.**
First, set the division of 42 by 65; that is, set 65 on the C scale opposite 42 on the D scale.* Move the hairline on indicator to 37 on the C scale. Read the result 239 on the D scale under the hairline. Since the fraction \( \frac{42}{65} \) is about \( \frac{2}{3} \), the result is about two-thirds of 37, or 23.9.

**Example:**

\( 273 \times 548 \)

Set 692 on the C scale opposite 273 on the D scale. Move the hairline to 548 on the C scale. Move the slide to set 692 on the C scale under the hairline. Read the result .628 on the D scale under the C index.

In general, to do computations of the type \( \frac{a \times c \times e \times g \ldots}{b \times d \times f \times h \ldots} \), set the rule to divide the first factor in the numerator \( a \) by the first factor in the denominator \( b \), move the hairline to the next factor in the numerator \( c \); move the slide to set next factor in denominator, \( d \), under the hairline. Continue moving hairline and slide alternately for other factors (e, f, g, b, etc.). Read the result on the D scale. If there is one more factor in the numerator than in the denominator, the result is under the hairline. If the number of factors in numerator and denominator is the same, the result is under the C index. Sometimes the slide must be moved so that one index replaces the other.*

**Example:**

\( 2.2 \times 2.4 \)

If the rule is set to divide 2.2 by 8.4, the hairline cannot be set over 2.4 of the C scale and at the same time remain on the rule. Therefore the hairline is moved to the C index (opposite 202 on the D scale) and the slide is moved end for end to the right (so that the left index falls under the hairline and over 202 on the D scale). Then the hairline is moved to 2.4 on the C scale and the result .63 is read on the D scale.

If the number of factors in the numerator exceeds the number in the denominator by more than one, the numbers may be grouped, as shown below. After the value of the group is worked out, it may be multiplied by the other factors in the usual manner.

\[
\left( \frac{a \times b \times c}{m \times n} \right) \times d \times e
\]

**PROPORTION**

Problems in proportion are very easy to solve. First notice that when the index of the C scale is opposite 2 on the D scale, the ratio \( 1 : 2 \) or \( \frac{1}{2} \) is at the same time set for all other opposite graduations; that is, \( 2 : 4 \), or \( 3 : 6 \), or \( 2.5 : 5 \), or \( 3.2 : 6.4 \), etc. It is true in general that for any setting the numbers for all pairs of opposite graduations have the same ratio. Suppose one of the terms of a proportion is unknown. The proportion can be written as \( \frac{a}{b} = \frac{c}{d} \), where \( a, b, \) and \( c \), are known numbers and \( x \) is to be found.

**Rule:** Set \( a \) on the C scale opposite \( b \) on the D scale. Under \( c \) on the C scale read \( x \) on the D scale.

**Example:** Find \( x \) if \( \frac{3}{4} = \frac{5}{x} \)

Set 3 on C opposite 4 on D. Under 5 on C read 6.67 on D.

The proportion above could also be written \( \frac{a}{b} = \frac{c}{d} \) or "inverted," and exactly the same rule could be used. Moreover, if C and D are interchanged in the above rule, it will still hold if "under" is replaced by "over." It then reads as follows:

Set \( a \) on the D scale opposite \( b \) on the C scale. Over \( c \) on the D scale read \( x \) on the C scale.

**Rule:** In solving proportions, keep in mind that the position of the numbers as set on the scales is the same as it is in the proportion written in the form \( \frac{a}{b} = \frac{c}{d} \).
Proportions can also be solved algebraically. Then \( \frac{a}{b} = \frac{c}{x} \) becomes \( x = \frac{bc}{a} \), and this may be computed as combined multiplication and division.

**SPECIAL GRADUATIONS—CIRCULAR MEASURE**

A special graduation on the C scale at \( \pi/4 = 0.7854 \) is especially convenient in finding the area or the diameter of a circle, and in similar problems. Since \( A = (\pi/4)d^2 \), where \( d \) is the diameter, the following rule applies.

**Rule:** To find the area \( A \) of a circle whose diameter \( d \) is known, set the right index of the C scale over \( d \) on the D scale. Move the hairline over .7854 mark on right hand section of B scale. Read area under hairline on A scale.

**Rule:** To find the diameter of a circle whose area \( A \) is known, set hairline over diameter on A scale (See page 19 for rule regarding section of A scale to use). Move slide until .7854 mark on right hand section of B scale is under hairline. Read diameter on D scale below right index of C scale.

A special graduation on the C and D scales at 57.3 is indicated by a small R. Since one radian = 57.3° (approximately), this R graduation is useful in changing radian measure to degree measure, and conversely.

**Rule:** To convert radians to degrees, set an index of the C scale to the number of radians on D. Under R on C read the number of degrees on D. To convert degrees to radians, set R on C over the number of degrees on D. At the index of C read the number of radians on D.

**EXAMPLES:**

(a) Convert \( \pi/2 \) radians to degrees. Set 2 on C over \( \pi \) on D. At the left-index of C read \( \pi/2 \), or \( 1.57 \), on D.

(b) Convert 30° to radians. Set R on C over 30 on D. At the index of C read 0.524 radians on D.

Note that this method puts the result on the D scale in convenient form for continued computation. In similar fashion, by interchange C and D and the words "under" and "over," in the above rules, the result can be put on the C scale.

### PART 2. USE OF CERTAIN SPECIAL SCALES

**THE CI AND DI SCALES**

It should be understood that the use of the CI and DI scales does not increase the power of the instrument to solve problems. In the hands of an inexperienced computer, however, these scales are used to reduce the number of settings or to avoid the awkwardness of certain settings. In this way the speed can be increased and errors minimized.

The CI scale on the slide is a C scale which increases from right to left. It may be used for finding reciprocals. When any number is set under the hairline on the C scale its reciprocal is found under the hairline on the CI scale, and conversely.

**EXAMPLES:**

(a) Find \( 1/2.4 \). Set 2.4 on C. Read .417 directly above on CI.

(b) Find \( 1/60.5 \). Set 60.5 on C. Read .0165 directly above on CI. Or, set 60.5 on C, read .0165 directly below on C.

The CI scale is useful in replacing a division by a multiplication. Since \( \frac{a}{b} = a \times \frac{1}{b} \), any division may be done by multiplying the numerator (or dividend) by the reciprocal of the denominator (or divisor). This process may often be used to avoid settings in which the slide projects far outside the rule.

**EXAMPLES:**

(a) Find \( 13.6 \div 87.5 \). Consider this as \( 13.6 \times 1/87.5 \). Set left index of the C scale on 13.6 of the D scale. Move hairline to 87.5 on the CI scale. Read the result, .155, on the D scale.

(b) Find \( 72.4 \div 1.15 \). Consider this as \( 72.4 \times 1/1.15 \). Set right index of the C scale on 72.4 of the D scale. Move hairline to 1.15 on the CI scale. Read 63.0 under the hairline on the D scale.

An important use of the CI scale occurs in problems of the following type.

**EXAMPLE:** Find \( \frac{13.6}{4.13 \times 2.79} \)

This is the same as \( 13.6 \times (1/2.79) \).

Set 4.13 on the C scale opposite 13.6 on the D scale. Move hairline to 2.79 on the CI scale, and read the result, 1.180, on the D scale.

By use of the CI scale, factors may be transferred from the numerator to the denominator of a fraction (or vice-versa) in order to make the settings more readily. Also, it is sometimes easier to get \( a \times b \) by setting the hairline on \( a \), pulling \( b \) on the CI scale under the hairline, and reading the result on the D scale under the index.

The DI scale (inverted D scale) below the D scale corresponds to the CI scale on the slide. Thus the D and DI scales together represent reciprocals. The DI scale has several important uses, of which the following is representative.
Expressions of the type \(1/X\), where \(X\) is some complicated expression or formula, may be computed by first finding the value of \(X\). If the result for \(X\) falls on \(D\), then \(1/X\) may be read under the hairline on \(DI\).

**Example:**

(a) Find \(\frac{1}{0.265 \times 138}\). Multiply \(0.265 \times 138\) using the \(C\) and \(D\) scales. Read the reciprocal \(0.0073\) under the hairline on the \(DI\) scale. Or set the hairline on \(265\) of the \(D1\) scale, pull \(138\) of the \(C\) scale under the hairline, and read the result on the \(D\) scale under the left index of the \(C\) scale. This is equivalent to writing the expression as \(\frac{1}{0.265 \times 138}\).

**ANSWERS**

**THE CF/\(\pi\) AND DF/\(\pi\) SCALES**

It should be understood that the use of the CF and DF scales does not increase the power of the instrument to solve problems. In the hands of an experienced operator, however, these scales are used to reduce the number of certain settings. In this way the speed can be increased and errors minimized.

When \(\pi\) on the \(C\) scale is opposite the right index of the \(D\) scale, about half the slide projects beyond the rule. If this part were cut off and used to fill in the opening at the left end, the result would be a "folded" \(C\) scale, or CF scale. Such a scale is printed at the top of the slide. It begins at \(\pi\) and the index is near the middle of the rule. The DF scale is similarly placed. Any setting of \(C\) on \(D\) is automatically set on \(CF\) and \(DF\). Thus if 3 on \(C\) is opposite 2 on \(D\), then 3 on \(CF\) is also opposite 2 on \(DF\). The CF and DF scales can be used for multiplication and division in exactly the same way as the \(C\) and \(D\) scales.

The most important use of the CF and DF scales is to avoid resetting the slide. If a setting of the indicator cannot be made on the \(C\) or \(D\) scale, it can be made on the \(CF\) or \(DF\) scale.

**EXAMPLES:**

(a) Find \(19.2 \times 6.38\). Set left index of \(C\) on 19.2 of \(D\). Note that 6.38 on \(C\) falls outside the \(D\) scale. Hence, move the indicator to 6.38 on the \(CF\) scale, and read the result 122.5 on the \(DF\) scale. Or set the index of \(CF\) on 19.2 of \(DF\). Move indicator to 6.38 on \(CF\) and read 122.5 on \(DF\).

(b) Find \(\frac{8.39 \times 9.65}{5.72}\). Set 5.72 on \(C\) opposite 8.39 on \(D\). The indicator cannot be moved to 9.65 of \(C\), but it can be moved to this setting on \(CF\) and the result, 44.15, read on \(DF\). Or the entire calculation may be done on the \(CF\) and \(DF\) scales.

These scales are also helpful in calculations involving \(\pi\) and \(1/\pi\). When the indicator is set on any number \(N\) on \(D\), the reading on \(DF\) is \(N\pi\). This can be symbolized as \((DF) = \pi(D)\). Then \((D) = \frac{(DF)}{\pi}\). This leads to the following simple rule.

**Rule:** If the diameter of a circle is set on \(D\), the circumference may be read immediately on \(DF\), and conversely.

**EXAMPLES:**

(a) Find 5.6\(\pi\). Set indicator over 5.6 on \(D\). Read 17.6 under hairline on \(DF\).

(b) Find 8/\(\pi\). Set indicator over 8 on \(DF\). Read 2.55 under hairline on \(D\).

(c) Find the circumference of a circle whose diameter is 7.2. Set indicator on 7.2 of \(D\). Read 22.6 on \(DF\).

(d) Find the diameter of a circle whose circumference is 121. Set indicator on 121 of \(DF\). Read 38.5 on \(D\).
Finally, these scales are useful in changing radians to degrees and conversely. Since \( \pi \text{ radians} = 180 \text{ degrees} \), the relationship may be written as a proportion \( \frac{\pi}{d} = \frac{180}{\pi} \), or \( \pi = \frac{d \cdot 180}{\pi} \).

**Rule:** Set 180 of C opposite \( \pi \) on D. To convert radians to degrees, move indicator to \( \pi \) (the number of radians) on DF, read \( d \) (the number of degrees) on CF; to convert degrees to radians, move indicator to \( d \) on CF, read \( \pi \) on DF.

There are also other convenient settings as suggested by the proportion. Thus one can set the ratio \( \pi/180 \) on the CF and DF scales and find the result from the C and D scales.

**Examples:**

(a) The numbers 1, 2, and 7.64 are the measures of three angles in radians.
Converting to degrees, set 180 of C on \( \pi \) of D. Move indicator to 1 on DF, read 57.3° on CF. Move indicator over 2 of DF, read 114.6°. Move indicator to 7.64 of DF. Read 437° on CF.

(b) Convert 30° and 83.2° to radians. Use the same setting as in (a) above.
Locate 36 on CF. Read 0.028 radians on DF. Locate 83.2 on CF. Read 1.45 radians on DF.

**THE CIF SCALE**

Like the other special scales the CIF scale does not increase the power of the instrument to solve problems. It is used to reduce the number of settings or to avoid the awkwardness of certain settings. In this way the speed can be increased and errors minimized.

The CIF scale is a folded CI scale. Its relationship to the CF and DF scales is the same as the relation of the CI scale to the C and D scales.

**Examples:**

(a) Find 68.2 \times 1.43. Set the indicator on 68.2 of the D scale. Observe that if the left index is moved to the hairline the slide will project far to the right. Hence merely move 14.3 on CI under the hairline and read the result 97.5 on D at the C index.

(b) Find 2.07 \times 8.4 \times 16.1. Set indicator on 2.07 on C. Move slide until 8.4 on CI is under hairline. Move hairline to 16.1 on C. Read 280 on D under hairline. Or set the index of CF on 8.4 of DF. Move indicator to 16.1 on CF, then move slide until 2.07 on CIF is under hairline. Read 280 on DF above the index of CF. Or set 16.1 on CI opposite 8.4 on D. Move indicator to 2.07 on C, and read 280 on D. Although several other methods are possible, the first method given is preferable.

**THE A AND B SCALES: Square Roots and Squares**

When a number is multiplied by itself the result is called the square of the number. Thus 25 or \( 5 \times 5 \) is the square of 5. The factor 5 is called the square root of 25. Similarly, since 12.25 = \( 3.5 \times 3.5 \), the number 12.25 is called the square of 3.5; also 3.5 is called the square root of 12.25. Squares and square roots are easily found on a slide rule.

**Square Roots:** To find square roots the A and D scales or the B and C scales are used.

**Rule:** The square root of any number located on the A scale is found below it on the D scale.

Also, the square root of any number located on the B scale (on the slide) is found on the C scale.

**Examples:** Find \( \sqrt{4} \). Place the hairline of the indicator over 4 on the left end of the A scale. The square root, 2, is read below on the D scale. Similarly the square root of 9 (or \( \sqrt{9} \)) is 3, found on the D scale below the 9 on the left end of the A scale.

**Reading the Scales:** The A scale is a contraction of the D scale itself. The D scale has been shrunk to half its former length and printed twice on the same line. To find the square root of a number between 0 and 10 the left half of the A scale is used (as in the examples above). To find the square root of a number between 10 and 100 the right half of the A scale is used. For example, if the hairline is set over 16 on the right half of the A scale (near the middle of the rule), the square root of 16, or 4, is found below it on the D scale.

In general, to find the square root of any number with an odd number of digits or zeros (1, 3, 5, 7, ...) the left half of the A scale is used. If the number has an even number of digits or zeros (2, 4, 6, 8, ...), the right half of the A scale is used. In these statements it is assumed that the number is not written in standard form.

The table below shows the number of digits or zeros in the number \( N \) and its square root, and also whether right or left half of the A scale should be used.

<table>
<thead>
<tr>
<th>ZEROS OR DIGITS</th>
<th>1, 3, 5, 7, ...</th>
<th>2, 4, 6, 8, ...</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \sqrt{N} )</td>
<td>( N ) 7 or 6</td>
<td>( N ) 5 or 4</td>
</tr>
<tr>
<td>3</td>
<td>1 or 2</td>
<td>3 or 4</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>3</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>

This shows that numbers from 1 up to 100 have one digit in the square root; numbers from 100 up to 10,000 have two digits in the square root, etc. Numbers which are less than 1 and have, for example, either two or three zeros, have only one zero in the square root. Thus \( \sqrt{0.004} = 0.0632 \), and \( \sqrt{0.0004} = 0.02 \).
EXAMPLES:

(a) Find \(\sqrt{248}\). This number has 3 (an odd number) digits. Set the hairline on 248 of the left A scale. Therefore the result on D has 2 digits, and is 15.75 approximately.

(b) Find \(\sqrt{563000}\). The number has 6 (an even number) digits. Set the hairline on 563 of the right A scale. Read the figures of the square root on the D scale as 75. The square root has 3 digits and is 750 approximately.

(c) Find \(\sqrt{0.0001382}\). The number of zeros is 4 (an even number). Set the hairline on 1382 of the right half of the A scale. Read the figures 309 on the D scale. The result has 2 zeros, and is 0.03990.

If the number is written in standard form, the following rule may be used. If the exponent of 10 is an even number, use the left half of the A scale and multiply the reading on the D scale by 10 to an exponent which is \(\frac{1}{2}\) the original. If the exponent of 10 is an odd number, move the decimal point one place to the right and decrease the exponent of 10 by one, then use the right half of the A scale and multiply the reading on the D scale by 10 to an exponent which is \(\frac{1}{2}\) the reduced exponent. This rule applies to either positive or negative exponents of 10.

EXAMPLES:

(1) Find the square root of \(3.56 \times 10^4\). Place hairline of indicator on 3.56 on the left half of the A scale and read 1.887 on the D scale. Then the square root is \(1.887 \times 10^2 = 188.7\).

(2) Find the square root of \(7.43 \times 10^{-5}\). Express the number as \(7.43 \times 10^{-4}\). Now place the hairline of the indicator over 743 on the right half of the A scale and read 8.62 on the D scale. Then the desired square root is \(8.62 \times 10^{-3}\).

All the above rules and discussion can be applied to the B and C scales if it is more convenient to have the square root on the slide rather than on the body of the rule.

Squares: To find the square of a number, reverse the process for finding the square root. Set the indicator over the number on the D scale and read the square of that number on the A scale; or set the indicator over the number on the C scale and read the square on the B scale.

EXAMPLES:

(a) Find \((1.73)^2\) or \(1.73 \times 1.73\). Locate 1.73 on the D scale. On the A scale find the approximate square 3.

(b) Find \((62800)^2\). Locate 628 on the D scale. Find 394 above it on the A scale. The number has 5 digits. Hence the square has either 9 or 10 digits. Since, however, 394 was located on the right half of the A scale, the square has the even number of digits, or 10. The result is 3,940,000,000.

(c) Find \((0.00254)^2\). On the A scale read 645 above the 254 of the D scale. The number has 3 zeros. Since 645 was located on the side of the A scale for "odd zero" numbers, the result has 7 zeros, and is 0.000000645.

THE K SCALE: Cube Roots and Cubes

Just below the D scale on the back of the rule is a scale marked with the letter K; this scale may be used in finding the cube or cube root of any number.

Rule: The cube root of any number located on the K scale is found directly above on the D scale.

EXAMPLE: Find the \(\sqrt[3]{8}\). Place the hairline of the indicator over the 8 at the left end of the K scale. The cube root, 2, is read directly above on the D scale.

Reading the scale: The cube root scale is directly below the D scale and is a contraction of the D scale itself. The D scale has been shrunk to one third its former length and printed three times on the same line. To find the cube root of any number between 0 and 10 the left third of the K scale is used. To find the cube root of a number between 10 and 100 the middle third is used. To find the cube root of a number between 100 and 1000 the right third of the K scale is used to locate the number.

In general to decide which part of the K scale to use in locating a number, mark off the digits in groups of three starting from the decimal point. If the left group contains one digit, the left third of the K scale is used; if there are two digits in the left group, the middle third of the K scale is used; if there are three digits, the right third of the K scale is used. In other words, numbers containing 1, 4, 7, \(\cdots}\) digits are located on the left third; numbers containing 2, 5, 8, \(\cdots\) digits are located on the middle third; and numbers containing 3, 6, 9, \(\cdots\) digits are located on the right third of the K scale. The corresponding number of digits or zeros in the cube roots are shown in the table below and whether the left, center or right section of the K scale should be used.

</table>

**Examples:**

(a) Find \( \sqrt[3]{6.4} \). Set hairline over 64 on the left most third of the K scale. Read 1.857 on the D scale.

(b) Find \( \sqrt[3]{64} \). Set hairline over 64 on the middle third of the K scale. Read 4 on the D scale.

(c) Find \( \sqrt[3]{640} \). Set hairline over 64 on the right most third of the K scale. Read 8.72 on the D scale.

(d) Find \( \sqrt[3]{6,400} \). Set hairline over 64 on the left third of the K scale. Read 18.57 on the D scale.

(e) Find \( \sqrt[3]{64,000} \). Set hairline over 64 on the middle third of the K scale. Read 40 on the D scale.

(f) Find \( \sqrt[3]{0.0064} \). Use the left third of the K scale, since the first group of three, or 0.006, has only one non-zero digit. The D scale reading is then 0.1857.

(g) Find \( \sqrt[3]{0.0064} \). Use the middle third of the K scale, reading 0.4 on D.

If the number is expressed in standard form it can either be written in ordinary form or the cube root can be found by the following rule.

**Rule:** Make the exponent of 10 a multiple of three, and locate the number on the proper third of the K scale. Read the result on the D scale and multiply this result by 10 to an exponent which is \( \frac{1}{3} \) the former exponent of 10.

**Examples:** Find the cube root of \( 6.9 \times 10^3 \). Place the hairline over 6.9 on the left third of the K scale and read 1.904 on the D scale. Thus the desired cube root is \( 1.904 \times 10^1 \). Find the cube root of \( 4.85 \times 10^7 \). Express the number as \( 48.5 \times 10^4 \) and place the hairline of the indicator over 48.5 on the middle third of the K scale. Read 3.65 on the D scale. Thus the desired cube root is \( 3.65 \times 10^2 \). Find the cube root of \( 1.33 \times 10^{-5} \). Express the number as \( 133 \times 10^{-4} \) and place the hairline over 133 on the right third of the K scale. Read 5.10 on the D scale. The required cube root is \( 5.10 \times 10^{-2} \).

**Cubes:** To find the cube of a number, reverse the process for finding cube root. Locate the number on the D scale and read the cube of that number on the K scale.

**Examples:**

(a) Find \( (1.37)^3 \). Set the indicator on 1.37 of the D scale. Read 2.57 on the K scale.

(b) Find \( (13.7)^3 \). The setting is the same as in example (a), but the K scale reading is 2570, or 1000 times the former reading.

(c) Find \( (2.9)^3 \) and \( (29)^3 \). When the indicator is on 2.9 of D, the K scale reading is 24.4. The result for 29 is therefore 2440.

(d) Find \( (6.3)^3 \). When the indicator is on 6.3 of D, the K scale reading is 250.

**Problems:**

1. \( 2.45^3 \)  
2. \( 56.1^3 \)  
3. \( 738^3 \)  
4. \( 164.5^3 \)  
5. \( 0933^3 \)  
6. \( \sqrt[3]{53} \)  
7. \( \sqrt[3]{71} \)  
8. \( \sqrt[3]{815} \)  
9. \( \sqrt[3]{0.0315} \)  
10. \( \sqrt[3]{525,000} \)  
11. \( \sqrt[3]{0.156} \)

**Answers:**

14.7  
176,600  
.402  
4,451,000  
.000812  
1.744  
4.14  
9.34  
.316  
80.7  
.538

**Combined Operations**

Many problems involve expressions like \( \sqrt[3]{ab} \), or \( (a \sin \theta)^3 \), etc. With a little care, many such problems involving combined operations may be easily computed. The list of possibilities is extensive, and it is no real substitute for the thinking needed to solve them. Consequently, only a few examples will be given.

The A and B scales may be used for multiplication or division in exactly the same way as the C and D scales. Since the scales are shorter, there is some loss in accuracy. Nevertheless, most computers employ the A and B scales (in conjunction with the C and D scales) to avoid extra steps which would also lead to loss of accuracy.

**Example:**

(a) Find \( \sqrt[3]{3.25 \times 4.18} \). First find the product \( 3.25 \times 4.18 \) using the left A and B scales. Set left index of B on 3.25 of A. Move indicator to 4.18 on B. Read the square root of this product under the hairline on D. The result is 3.69 approximately.

(b) Find \( 1.63 \times 5.41^3 \). Set the left index on B under 1.63 of A. Move the indicator to 5.41 on C. Read the result 47.7 under the hairline on A.

(c) Find \( 5^3 \) or \( (\sqrt[3]{5})^3 \). This is the same as \( (\sqrt[3]{5}) \). Hence set the indicator on 5 of the left A scale. Read 11.2 on the middle K scale under the hairline.

(d) Find \( 24^3 \) or \( (\sqrt[3]{24})^3 \). Set the indicator on 24 of the middle K scale. Read the result after squaring as 8.3 on the A scale under the hairline.
The L Scale: LOGARITHMS

The L scale represents logarithms to the base 10, or common logarithms. The logarithm of a number is the exponent to which a given base must be raised to produce the number. For example, \( \log 10^2 = 2.00 \), \( \log 10^3 = 3.00 \), etc. A logarithm consists of two parts. The characteristic is the part on the left of the decimal point. The mantissa is the decimal fraction part on the right of the decimal point. The L scale is used for finding the mantissa of the logarithm (to the base 10) of any number. The mantissa of the logarithm is the same for any series of digits regardless of the location of the decimal point.

The position of the decimal point in the given number determines the characteristic of the logarithm, and conversely. The following rules apply in determining the characteristic:

1. For 1, and all numbers greater than 1, the characteristic is one less than the number of places to the left of the decimal point in the given number.
2. For numbers smaller than 1, that is for decimal fractions, the characteristic is negative. Its numerical value is one more than the number of zeros between the decimal point and the first significant figure in the given number.

The application of these rules is illustrated by the following chart:

<table>
<thead>
<tr>
<th>Digits to Left of Decimal Point</th>
<th>Zeros to Right of Decimal Point*</th>
</tr>
</thead>
<tbody>
<tr>
<td>Digits in Number 1 2 3 4 5 6 7 8</td>
<td>Zeros in Number 0 1 2 3 4 5 6 7 8</td>
</tr>
<tr>
<td>Characteristic 0 1 2 3 4 5 6 7</td>
<td>Characteristic -1 2 3 4 5 6 7 8 9</td>
</tr>
</tbody>
</table>

*Note: Count only zeros between decimal point and first significant figure.

Rule: Locate the number on the D scale (when L scale is on top or bottom stator), and read the mantissa of its logarithm (to the base 10) on the L scale. Determine the characteristic. If the L scale is on the slide, use the C scale instead of the D scale.

Example: Find the logarithm of 425.

Set the hairline over 425 on the D scale. Read the mantissa of the logarithm (0.628) on the L scale. Since the number 425 has 3 digits, the characteristic is 2 and the logarithm is 2.628.

If the logarithm of a number is known, the number may be found by reversing the above process. The characteristic is ignored until the decimal point is to be placed in the number.

Example: Find \( x \), if \( \log x = 3.248 \).

Set the hairline over 248 on the L scale. Above it read the number 177 on the D scale. Since the characteristic is 3, there are 4 digits in the number, \( x = 1770 \).

Example: Find the logarithm of 0.00627.

Opposite 627 on the D scale find .797 on the L scale. Since the number has 3 zeros, the characteristic is -4 and the logarithm is \(-4 + .797 = 6.797\) and is usually written 6.797-10.

Note that the mantissa of a logarithm is always positive but the characteristic may be either positive or negative. In computations, negative characteristics are troublesome and frequently are a source of error. It is customary to handle the difficulty by not actually combining the negative characteristic and positive mantissa. For example, if the characteristic is \(-4\) and the mantissa is .797, the logarithm may be written 0.797 \(-4\). This same number may also be written 6.797 \(-10\), or 5.797 \(-9\) and in other ways as convenient. In each of these forms if the integral parts are combined, the result is \(-4\). Thus 0 \(-4\) = \(-4\), 6 \(-10\) = \(-4\), 5 \(-9\) = \(-4\). The form which shows that the number 10 is to be subtracted is the most common.

Examples:

\[
\begin{align*}
\log 1 &= 10.000 - 10 \\
\log .4 &= 9.602 - 10 \\
\log .0004 &= 6.602 - 10 \\
\end{align*}
\]

Problems:

\[
\begin{align*}
\text{Log} 3.26 &= .513 \\
\text{Log} 735 &= 2.866 \\
\text{Log} .0194 &= 8.288 - 10 \\
\text{Log} 54800 &= 4.739 \\
\text{Log} X &= 2.052 \\
\text{Log} X &= 9.831 - 10 \\
\text{Log} X &= .357 \\
\text{Log} X &= 1.598 \\
\text{Log} X &= 7.154 - 10 \\
\end{align*}
\]

The S, T, and ST Scales: TRIGONOMETRY

The branch of mathematics called trigonometry arose historically in connection with the measurement of triangles. However, it now has many other uses in various scientific fields.

Some important formulas from trigonometry will be listed here for ready reference.

The trigonometric ratios may be defined in terms of a right triangle as follows:

\[
\begin{align*}
\text{Sine of angle } A &= \frac{\text{side opposite}}{\text{hypotenuse}} \quad \text{written } \sin A = \frac{a}{h}; \\
\text{Cosine of angle } A &= \frac{\text{side adjacent}}{\text{hypotenuse}} \quad \text{written } \cos A = \frac{b}{h}; \\
\text{Tangent of angle } A &= \frac{\text{side opposite}}{\text{side adjacent}} \quad \text{written } \tan A = \frac{a}{b}; \\
\text{Cotangent of angle } A &= \frac{\text{side adjacent}}{\text{side opposite}} \quad \text{written } \cot A = \frac{b}{a}; \\
\text{Secant of angle } A &= \frac{\text{hypotenuse}}{\text{side adjacent}} \quad \text{written } \sec A = \frac{h}{b}; \\
\text{Cosecant of angle } A &= \frac{\text{hypotenuse}}{\text{side opposite}} \quad \text{written } \csc A = \frac{h}{a}.
\end{align*}
\]
These ratios are functions of the angle. The definitions may be extended to cover cases in which the angle $A$ is not an interior angle of a right triangle, and hence may be greater than 90 degrees. Note that the sine and cosecant are reciprocals, as are the cosine and secant, and the tangent and cotangent. Therefore,

$$\sin A = \frac{1}{\cosec A}, \quad \text{and} \quad \cosec A = \frac{1}{\sin A};$$

$$\tan A = \frac{1}{\cot A}, \quad \text{and} \quad \cot A = \frac{1}{\tan A};$$

$$\cos A = \frac{1}{\sec A}, \quad \text{and} \quad \sec A = \frac{1}{\cos A}.$$ 

When the sum of two angles equals 90°, the angles are complementary.

$$\sin A = \cos (90° - A),$$

$$\cos A = \sin (90° - A),$$

$$\tan A = \cot (90° - A),$$

$$\cot A = \tan (90° - A).$$

When the sum of two angles equals 180°, the angles are supplementary.

$$\sin (180° - A) = \sin A,$$

$$\cos (180° - A) = -\cos A,$$

$$\tan (180° - A) = -\tan A.$$

The following laws are applicable to any triangle.

$$A + B + C = 180°$$

Law of sines: $$\frac{\sin A}{a} = \frac{\sin B}{b} = \frac{\sin C}{c}$$

Law of cosines: $$a^2 = b^2 + c^2 - 2bc \cos A$$

THE S SCALE: Sines and Cosines

The scale marked S is used in finding the approximate sine or cosine of any angle between 3.7 degrees and 90 degrees. Since $\sin x = \cos (90° - x)$, the same graduations serve for both sines and cosines. Thus, $\sin 6° = \cos (90° - 6°) = \cos 84°$. The numbers printed at the right of the long scale are read when sine is to be found. Those printed at the left are used when cosines are to be found. On the slide rule, angles are divided in decimals instead of into minutes and seconds. Thus $12.7°$ is represented by the 7th small graduation to the right of the graduation marked 78/12.

Sines (or cosines) of all angles on the S scale have no digits or zeros; the decimal point is at the left of figures read from the C (or D) scale.

Rule: To find the sine of an angle on the S scale, set the hairline on the graduation which represents the angle. (Remember to read sines from left to right and the numbers to the right of the graduation are for sines). Read the sine on the C scale under the hairline. If the slide is placed so that the C and D scales are exactly together, the sine can also be read on the D scale, and the mantissa of the logarithm of the sine (log sin) may be read on the L scale.

EXAMPLE:

(1) Find $\sin 15° 30'$ and $\log \sin 15°30'$, Set left index of C scale over left index of D scale. Set hairline on 15.5° (i.e., 15°30') on S scale. Read sine $15.5° = .267$ on C or D scale. Read mantissa of $\log \sin 15.5° = .427$ on L scale. According to the rule for characteristics of logarithms, this would be $9.427 - 10$.

Rule: To find the cosine of an angle on the S scale, set the hairline on the graduation which represents the angle. (Remember to read cosines from right to left and the numbers to the left of the graduation are for cosines). Read the cosine on the C scale under the hairline. If the slide is placed so that the C and D scales are exactly together, the cosine can also be read on the D scale, and the mantissa of the cosine (log cos) may be read on the L scale.

EXAMPLE:

(1) Find $\cos 42° 15'$ and $\log \cos 42° 15'$, Set left index of C scale over left index of D scale. Set hairline on 42.25° (i.e., 42°15') on S scale. Read $\cos 42.25° = .740$ on C or D scale. Read mantissa of $\log \cos 42.25° = .869$ on L scale. According to rule for characteristics of logarithms, this would be $9.869 - 10$.

Finding the Angle

If the value of a trigonometric ratio is known, and the size of the angle less than 90° is to be found, the above rules are reversed. The value of the ratio is set on the C scale, and the angle itself read on the S scale.

EXAMPLES:

(a) Given $\sin x = .465$, find $x$. Set indicator on 465 of C scale, read $x = 27.7°$ on the S scale.

(b) Given $\cos x = .289$, find $x$. Set indicator on 289 on C scale. Read $x = 73.2°$ on the S scale.

PROBLEMS:

1. $\sin 9.6°$ =  .167
2. $\sin 37.2°$ =  .605
3. $\sin 79.0°$ =  .982
4. $\cos 12.2°$ =  .977
5. $\cos 28.6°$ =  .878
6. $\cos 37.2°$ =  1.000
7. $\cos 15.8°$ =  .374
8. $\sec 19.3°$ =  5.68
   Note: $\cosec \theta = \frac{1}{\sin \theta}$
9. $\sin \theta = .1737$; $\theta = 10°$
10. $\sin \theta = .98$; $\theta = 78°$
11. $\sin \theta = .472$; $\theta = 28.2°$
12. $\cos \theta = .982$; $\theta = 10.8°$
13. $\cos \theta = .317$; $\theta = 71.5°$
14. $\cos \theta = .242$; $\theta = 76°$
THE T SCALE: Tangents and Cotangents

The T scale, together with the C or CI scales, is used to find the value of the tangent or cotangent of angles between 5.7° and 84.3°. Since tan x = cot (90° - x), the same graduations serve for both tangents and cotangents. For example, if the indicator is set on the graduation marked 60°, the corresponding reading on the C scale is .577, the value of tan 30°. This is also the value of cot 60°, since tan 30° = cot (90° - 30°) = cot 60°. Moreover, tan x = 1/cot x; in other words, the tangent and cotangent of the same angle are reciprocals. Thus for the same setting, the reciprocal of cot 60°, or 1/.577, may be read on the CI scale as 1.732. This is the value of tan 60°. These relations lead to the following rule.

Rule: Set the angle value on the T scale and read
(i) tangents of angles from 5.7° to 45° on C,
(ii) tangents of angles from 45° to 84.3° on CI,
(iii) cotangents of angles from 45° to 84.3° on C,
(iv) cotangents of angles from 5.7° to 45° on CI.

If the slide is set so that the C and D scales coincide, these values may also be read on the D scale. Care must be taken to note that the T scale readings for angles between 45° and 84.3° increase from right to left.

In case (i) above, the tangent ratios are all between 0.1 and 1.0; that is, the decimal point is at the left of the number as read from the C scale.

In case (ii), the tangents are greater than 1.0, and the decimal point is placed to the right of the first digit as read from the CI scale. For the cotangent ratios in cases (iii) and (iv) the situation is reversed. Cotangents for angles between 45° and 84.3° have the decimal point at the left of the number read from the C scale. For angles between 5.7° and 45° the cotangent is greater than 1 and the decimal point is to the right of the first digit read on the CI scale. These facts may be summarized as follows.

Rule: If the tangent or cotangent ratio is read from the C scale, the decimal point is at the left of the first digit read. If the value is read from the CI scale, it is at the right of the first digit read.

EXAMPLES:
(a) Find tan x and cot x when x = 9°50'. First note that 50' = 50/60 of 1 degree = .83°, approximately. Hence 9°50' = 9.83° on the T scale. Read tan x = .173 on the C scale, and read cot x = .577 on the CI scale.
(b) Find tan x and cot x when x = 68.6°. Locate x = 68.6° on the T scale reading from right to left. Read 255 on the CI scale. Since all angles greater than 45° have tangents greater than 1 (that is, have one digit as defined above), tan x = 2.55. Read cot 68.6° = .392 on the C scale.

Finding the Angle

If the value of the trigonometric ratio is known, and the size of the angle less than 90° is to be found, the above rules are reversed. The value of the ratio is set on the C or CI scale, and the angle itself read on the T scale.

EXAMPLES:
(a) Given tan x = .321, find x. Set 321 on the C scale, read 17.9° on the T scale.
(b) Given tan x = 2.66, find x. Set 266 on the CI scale, read x = 69.4° on the T scale.
(c) Given cot x = .630, find x. Set .630 on the C scale, read x = 57.8° on the T scale.
(d) Given cot x = 1.865, find x. Set 1865 on the CI scale, read 28.2° on the T scale.

PROBLEMS:
1. tan 18.6° .337
2. tan 66.4° 2.29
3. cot 31.7° 1.619
4. cot 83.85° .1078
5. tan θ = 1.173 θ = 49.55°
6. cot θ = .387 θ = 68.84°

THE ST SCALE: Small Angles

The sine and the tangent of angles of less than about 5.7° are so nearly equal that a single scale, marked ST, may be used for both. The graduation for 1° is marked with the degree symbol (°). To the left of it the primary graduations represent tenths of a degree. The graduation for 2° is just about in the center of the slide. The graduations for 1.5° and 2.5° are also numbered.

Rule: For small angles, set the indicator over the graduation for the angle on the ST scale, then read the value of the sine or tangent on the C scale. Sines or tangents of angles on the ST scale have one zero.

EXAMPLES:
(a) Find sin 2° and tan 2°. Set the indicator on the graduation for 2° on the ST scale. Read sin 2° = .0340 on the C scale. This is also the value of tan 2° correct to three digits.
(b) Find sin 0.94° and tan 0.94°. Set the indicator on 0.94 of ST. Read sin 0.94° = tan 0.94° = .0164 on the C scale.
Since \( \cot x = 1/\tan x \), the cotangents of small angles may be read on the CI scale. Moreover, tangents of angles between 84.3° and 89.42° can be found by use of the relation \( \tan x = \cot (90 - x) \). Thus \( \cot 2^\circ = 1/\tan 2^\circ = 28.6 \), and \( \tan 88^\circ = \cot 2^\circ = 28.6 \). Finally, it may be noted that \( \csc x = 1/\sin x \), and \( \sec x = 1/\cos x \). Hence the value of these ratios may be readily found if they are needed. Functions of angles greater than 90° may be converted to equivalent (except for sign) functions in the first quadrant.

**Examples:**

(a) Find \( \cot 1.41^\circ \) and \( \tan 88.59^\circ \). Set indicator at \( 1.41^\circ \) on ST. Read \( \cot 1.41^\circ = \tan 88.59^\circ = 40.7 \) on CI.

(b) Find \( \csc 21.8^\circ \) and \( \sec 21.8^\circ \). Set indicator at \( 21.8^\circ \) on the S scale. Read \( \csc 21.8^\circ = 1/\sin 21.8^\circ = 2.69 \) on CI. Set indicator on 68.2° of the S scale (or 21.8° reading from right to left), and read \( \sec 21.8^\circ = 1.077 \) on the CI scale.

When the angle is less than 0.57° the approximate value of the sine or tangent can be obtained directly from the C scale by the following procedure.

Read the ST scale as though the decimal point were at the left of the numbers printed, and the C scale (or D, CI, etc.) with the decimal point one place to the left of where it would normally be. Thus \( \sin 0.2^\circ = 0.00049; \tan 0.16^\circ = 0.002079 \), read on the C scale.

Two seldom used special graduations are also placed on the ST scale. One is indicated by a longer graduation found just to the left of the graduation for \( 2^\circ \) at about 1.97°. When this graduation is set opposite any number of minutes on the D scale, the sine (or the tangent) of an angle of that many minutes may be read on the D scale under the C index.

\[ \sin 0^\circ = 0, \text{ and } \sin 1^\circ = 0.00029, \text{ and for small angles the sine increases by } 0.00029 \text{ for each increase of } 1^\circ \text{ in the angle. Thus } \sin 2^\circ = 0.00058, \text{ sin } 3^\circ = 0.0100, \text{ and the sines of all angles between } 3.44^\circ \text{ and } 34.4^\circ \text{ have two zeros. Sines of angles between } 34.4^\circ \text{ and } 34.4^\circ \text{ (or } 57.3^\circ) \text{ have one zero. The tangents of these small angles are very nearly equal to the sines.}

**Example:** Find \( \sin 6^\circ \). With the hairline set the “minute graduation” opposite 6 on the D scale. Read 175 on the D scale under the C index. Then \( \sin 6^\circ = 0.01015 \).

The second special graduation is also indicated by a longer graduation located at about 1.18°. It is used in exactly the same way as the graduation for minutes. \( \sin 1^\circ = 0.000048, \) approximately, and the sine increases by this amount for each increase of \( 1^\circ \) in the angle, reaching \( 0.00029 \) for \( \sin 60^\circ \) or \( \sin 1^\circ \).

**Trigonometric Computations**

Many formulas include both trigonometric ratios and other factors. By using several different scales such computations are easily done.

**Examples:**

(a) Find the length of the legs of a right triangle in which the hypotenuse is 48.3 ft. and one acute angle is 25° 20'.

(b) One angle of a right triangle is \( 68.3^\circ \), and the adjacent side is 18.6 ft. long. Find the other side and the hypotenuse.

\[ a = 18.6 \tan 68.3^\circ \text{ or } 18.6/\cot 68.3^\circ \]
\[ c = 18.6/\cos 68.3^\circ \]

To find \( a \), set the indicator on 18.6 of the D scale, pull the slide until 68.3 of the T scale (read from right to left) is under the hairline, and read \( a = 46.7^\circ \) on the D scale under the right index of the C scale. To find \( c \), pull the slide until 68.3 of the D scale (read from right to left) is under the hairline (which remains over 18.6), and read the result 50.3 on the D scale at the right index.

This problem may also be solved by the law of sines, namely,

\[ \frac{\sin A}{a} = \frac{\sin B}{b} = \frac{\sin C}{c}, \text{ or } \frac{\sin 68.3^\circ}{a} = \frac{\sin 21.7^\circ}{18.6} \]

Set 21.7° on S opposite 18.6 on D. Read \( c = 50.3 \) on D under 1 of C. Move indicator to 68.3° on S, read 46.7 under the hairline on D.

(c) Find one side and two angles of an obtuse triangle when two sides and an included angle are known.

Given: \( c = 428 \); \( b = 537 \); \( A = 32.6^\circ \)

Find: \( a \), \( B \), and \( C \).

Construct: Line \( h \) from the vertex of \( B \) perpendicular to \( AC \). This divides \( \triangle ABC \) into 2 right triangles.

Then \( h = c \sin A \), from the formula for sine of an angle.

Set right index of C over 428 on D and read \( h = 231 \) on D scale opposite 32.6° on S scale. Also,

\[ m = \frac{h}{\tan A}, \text{ from formula for tangent of an angle.} \]
Opposite h (231) on D scale set 32.6° on T scale, and read m = 361 on D scale opposite right index on C scale. Since m is now known, \( n = b - m = 176 \).

\[
\tan C = \frac{h}{n}, \text{ from formula for tangent of an angle.}
\]

Opposite 231 on D scale set 176 on C scale and read 1.312, or \( \tan C \) on D opposite left index of C scale. Set 1.312 on CI (see rule page 28), and read \( C = 52.7° \) on T. Finally,

\[
a = \frac{h}{\sin C} \text{ from formula for sine of an angle.}
\]

Set index of C over index of D and move hairline to 52.7° on S. Move right index of C under hairline. Move hairline to 231 on CI. Read \( a = 290 \) on D1.

Since \( A + B + C = 180° \), then \( B = 180° - (A + C) = 180° - 32.6° - 52.7° = 94.7° \).

**PART 3 - ELEMENTARY VECTOR METHODS**

**COMPLEX NUMBERS AND VECTORS**

A vector quantity is one which has both magnitude and direction. For example, force and velocity are vector quantities. A quantity which has magnitude only is called a scalar. For example, mass is a scalar. Vector quantities are often represented by directed straight line segments. The length of the segment represents the magnitude in terms of a selected scale unit. The segment has an initial point A and a terminal point B, and direction is usually indicated by an arrowhead at B pointing in the same direction as the motion of a point which travels from A to B. In Fig. 11, three vectors are represented; namely AB of magnitude 5, AC of magnitude 4, and CB of magnitude 3. Vectors AB and AC have the same initial point, A, and form an angle, \( \angle CAB \), of 36.9°. The initial point of vector CB is at the terminal point of AC. Vectors CB and AB have the same terminal point.

Operations with vectors (for example, addition and multiplication) are performed according to special rules. Thus in Fig. 11, AB may be regarded as the vector sum of AC and CB. AB is called the resultant of AC and CB; the latter are components of AB, and in this case are at right angles to each other. It is frequently desirable to express a given vector in terms of two such components at right angles to each other. Conversely, when the components are given, it may be desirable to replace them with the single resultant vector.

In algebra, the complex number \( x + iy \), where \( i = \sqrt{-1} \), is represented by a point \( P (x, y) \) in the complex plane, using a coordinate system in which an axis of "pure imaginary" numbers, OY, is at right angles to an axis of "real" numbers, OX.

The same point can be expressed in terms of polar coordinates \((r, \theta)\) in which the radius vector OP from the origin of coordinates has length \( r \) and makes an angle \( \theta \) with the X-axis. The two systems of representation are related to each other by the following formulas:

\[
\begin{align*}
(1) \quad x &= r \cos \theta, \\
(3) \quad \tan \theta &= \frac{y}{x} \quad \text{or} \quad \theta = \arctan \frac{y}{x} \\
(2) \quad y &= r \sin \theta, \\
(4) \quad r &= \sqrt{x^2 + y^2}
\end{align*}
\]

Finally, the complex number \( x + iy \) may be regarded as a vector given in terms of its components \( x \) and \( y \) and the complex operator \( i = \sqrt{-1} \). In practical work the symbol \( j \) is preferred to \( i \); to avoid confusion with the symbol often used for the current in electricity.

The "Euler identity" \( e^{i\theta} = \cos \theta + j \sin \theta \) can be proved by use of the series expansions of the functions involved. Then \( re^{i\theta} \) is an exponential representation of the complex number \( x + iy \), since \( re^{i\theta} = r \cos \theta + j \sin \theta = x + jy \).

The notation is often simplified by writing \( r/\theta \) in place of \( re^{i\theta} \).

If two or more complex numbers are to be added or subtracted, it is convenient to have them expressed in the form \( x + iy \), since if \( N_1 = x_1 + iy_1 \) and \( N_2 = x_2 + iy_2 \), then \( N_1 + N_2 = (x_1 + x_2) + j(y_1 + y_2) \). If, however, two or more complex numbers are to be multiplied, it is convenient to have them expressed in the exponential form. Then if \( N_1 = re^{i\theta_1} \) and \( N_2 = se^{i\theta_2} \), then \( N_1N_2 = rs(e^{i(\theta_1+\theta_2)}) \) or \( (r_1/\theta_1)(s_2/\theta_2) = r_1s_2/\theta_1 + \theta_2 \).

It is therefore necessary to be able to change readily from either of these representations of a complex number to the other.

**Changing from Components to Exponential Form**

If a complex number \( x + iy \) (or vector in terms of perpendicular components) is given, the problem of changing to the form \( r/\theta \) is equivalent to finding the hypotenuse and one acute angle of a right triangle. The formulas

\[
\begin{align*}
\tan \theta &= \frac{y}{x}, \\
\tan \theta &= \frac{3}{4}, \text{ or } \theta = \arctan \frac{3}{4}
\end{align*}
\]

are the basis of the solution. Thus if \( N = 4 + j3 \), when \( 4 \) of \( C \) is set opposite 3 of \( D \), the value of the ratio \( \frac{3}{4} = 0.75 \) is read on \( D \) under the C index.
If the indicator is set at the index, and the slide moved so that .75 is under the hairline, the value of $\theta = 36.9^\circ$ may be read on the T scale. Then $p \times 3/36.9$ may be computed by moving the indicator to 3 on the D scale, pulling 36.9 on the S scale under the hairline, and reading $p = .5$ on the D scale opposite the right index of C. However, this method involves several unnecessary settings and is thus more subject to error than the method given in the general rule below.

Observe that if $x$ and $y$ are both positive and $x = y$, then $\tan \theta = 1$ and $\theta = 45^\circ$. If $x < y$, then $\theta < 45^\circ$; if $y > x$, then $\theta > 45^\circ$. Thus if $y < x$, the T scale is read from left to right. If $y > x$, the T scale is read from right to left.

**Rule:** (i) To the larger of the two numbers ($x, y$) on D set an index of the slide. Set the indicator over the smaller value on D and read $\theta$ on the T scale. If $y < x$, then $\theta < 45^\circ$. If $y > x$, then $\theta > 45^\circ$, and is read from right to left (or on the left of the graduation mark).

(ii) Move the slide until $\theta$ on scale S is under the indicator, reading S on the same side of the graduation as in (i). Read $p$ on D at the index of the C-scale.

Observe that the reading both begins and ends at an index of the slide. By this method the value of the ratio $y/x$ occurs on the C (or CI) scale of the slide over the smaller of the two numbers, and the angle may be read immediately on the T scale without moving the slide. In using any method or rule, it is wise to keep a mental picture of the right triangle in mind in order to know whether to read $\theta$ on the T or on the ST scale. Thus if the ratio $y/x$ is a small number, the angle $\theta$ is a small angle, and must be read on the ST scale. To be precise, if $y/x < 0.1$, the ST scale must be used. Similarly, if the ratio $y/x > 10$, the angle $\theta$ will be larger than $84.3^\circ$ and cannot be read on the T scale. The complementary angle $\phi = (90 - \theta)$ will, however, then be on the ST scale, and then $\theta$ may be found by subtracting the reading on the ST scale from $90^\circ$, since $\theta = 90 - \phi$.

**Examples:**

(a) Change $2 + j3.46$ to exponential or “vector” form. Note $\theta > 45^\circ$, since $y > x$ (or 3.46 > 2). Set right index of S opposite 3.46 on D. Move indicator to 2 on D. Read $\theta = 60^\circ$ on T at the left of the hairline. Move slide until 60° on S scale is under the hairline (numerals on the left), and read $p = 4$ on the D scale at the C-index. Then $2 + j3.46 = 4\times0.60 = 4/60^\circ$.

(b) Change $3 + j2$ to exponential or vector form. Note that $\theta < 45^\circ$ since $x < y$ (second component less than first). Set right index of S over 3 on D. Move indicator to 2 on D, read $\theta = 53.7^\circ$ on T (use numerals on the right-hand side of graduations). Move slide until 53.7° on Scale S is under the hairline (numerals on right), and read 3.60 on the D scale at the C index. Hence $3 + j2 = 3.60/53.7^\circ$.

(c) Change $2.34 + j1.4$ to exponential form. Since $y < x$, then $\theta < 45^\circ$. Moreover, the ratio $y/x$ is a small number (actually about .66). Since the tangent has one zero, the angle may be read on the ST scale. Set right index of S opposite 2.34 on D. Move indicator to .14 on D. Read $\theta = 3.43^\circ$ on ST. The slide need not be moved. The value of $p$ is approximately 2.34. In other words, the angle is so small that the hypotenuse is approximately equal to the longer side. Then $2.34 + j1.4 = 2.34/3.43$.

(d) Change $1.08 + j20.5$ to exponential form. Here $y > x$, so that $\theta > 45^\circ$. But $\theta = 26.5^\circ > 10$. Set right index of S on 26.5 of D. Move indicator to 1.08 of D. Read $\theta = 2.34^\circ$ on ST. The slide need not be moved. The value of $p$ is approximately 26.5. Then $\theta = 90 - 2.34^\circ = 87.66^\circ$. Hence $26.5/87.66^\circ$ is the required form.

The following method of changing $x + yj$ to the form $p/x$ using the DI scale is sometimes easier to use than methods based on the D scale.

**Rule:** (i) To the smaller of the two numbers ($x, y$) on D set an index of the slide. Set indicator over the larger value on DI and read $\theta$ on the T scale. If $y < x$, then $\theta < 45^\circ$. If $y > x$, then $\theta > 45^\circ$ and is read from right to left (or on the left of the graduation mark).

(ii) Move the indicator over $\theta$ on scale S (or ST), reading S on the same side of the graduation as in (i). Read $p$ on DI under the hairline.

**Examples:**

(a) Change $2 + j3.46$ to exponential form. Note that $y > x$ since 3.46 > 2, and hence $\theta > 45^\circ$. Set right index of C over 2 on DI. Move indicator to 3.46 on DI. Read $\theta = 60^\circ$ on T. Move indicator to 60° on S. Read $p = 4$ on DI. Hence $2 + j3.46 = 4/60^\circ$.

(b) Change $114 + j20$ to exponential form. Here $y < x$, so $\theta < 45^\circ$. Set left index of C over 20 on DI. Move indicator to 114 on DI. Read $\theta = 99.5^\circ$ on T. Move hairline to 99.5° on S. Read $p = 110$ on DI. Hence $114 + j20 = 110/99.5^\circ$.

It will be observed that this rule is, in general, easy to use. In step (i) the value of $\tan \theta$ for $\theta < 45^\circ$ may be observed under the hairline on the C scale, and the value of $\tan \theta$ for $\theta > 45^\circ$ under the hairline on CI.

It may be noted that the rule given first (using the D scale) obtains the result in example (b) above without having the slide project far to the right. Thus, it appears that the relative advantages of the two methods depend in part upon the problem.

If $x$ and $y$ are both positive, $\theta < 90^\circ$. If $x$ and $y$ are not both positive, the resultant vector does not lie in the first quadrant, and $\theta$ is not an acute angle. In using the slide rule, however, $x$ and $y$ must be treated as both positive. It is therefore necessary to correct $\theta$ as is done in trigonometry when an angle is not in the first quadrant.

**Examples:**

(a) Find the angle between the X-axis and the radius vector for the complex number $-4 + j3$. First solve the problem as though both components were positive. The angle $\theta$ obtained is $36.9^\circ$. In this case the required angle is $180^\circ - \theta = 180^\circ - 36.9^\circ = 143.1^\circ$. Hence $-4 + j3 = 5/143.1^\circ$.

Similarly for $-4 - j3$, the required angle is $180^\circ + \theta = 180^\circ + 36.9^\circ = 216.9^\circ$, so $-4 - j3 = 5/216.9^\circ$.

For $-j3$ the required angle is $90^\circ - \theta = 90^\circ - 32.31^\circ = 57.69^\circ$, so $-j3 = 5/57.69^\circ$, which may also be expressed in terms of a negative angle as $5/36.9^\circ$. 

Fig. 14
(b) Change \(17.2 - j6.54\) to exponential form. Here the ratio \(y/x\) is negative so \(\theta\) can be expressed as a negative angle. In numerical value \(y < x\), so the numerical or absolute value of \(\theta < 45^\circ\). Set left index of S opposite 17.2 on D. Move indicator over 6.54 of D, read \(\theta = 20.8^\circ\) on T. Pull 20.8 of S under hairline, read 18.4 on D at left index. Hence \(17.2 - j6.54 = 18.4 \div -20.8^\circ\), or \(18.4/339.2^\circ\).

**Changing from Exponential Form to Components:**

The process of changing a complex number or vector from the form \(pe^{j\theta}\) to the form \(x + jy\) depends upon the formulas \(x = \rho \cos \theta, y = \rho \sin \theta\). These are simple multiplications using the C, D, and S (or ST) scales.

**Rule:** Set an index of the S scale opposite \(\rho\) on the D scale. Move indicator to \(\theta\) on the S (or ST) scale, reading from left to right (sines). Read \(y\) on the D scale. Moving indicator to \(\theta\) on the S (or ST) scale, reading from right to left (cosines), read \(x\) on the D scale.

If \(\theta > 90^\circ\) or \(\theta < 0\), it should first be converted to the first quadrant, and the proper negative signs must later be associated with \(x\) or \(y\).

**Examples:**

(a) Change \(4/60^\circ\) to component form. Set right index of S on 4 of D. Move indicator to 60 on S (reading scale from left to right). Read 3.46 on D under hairline. Move indicator to 60 on S, reading scale from right to left (cosines). Read 2 on D under hairline. Hence \(4/60^\circ = 2 + j3.46\).

(b) Change \(16.3/15.4^\circ\) to the \(x + jy\) form. Set left index of S on 16.3 of D. Move indicator to 15.4 of S, read 4.33 on D. Since 15.4 reading from right to left is off the D scale, exchange indices so the right index of C is opposite 15.3 of D. Move indicator to 15.4 of S, and read 15.7 on D. Hence \(16.3/15.4^\circ = 15.7 + j4.33\).

(c) Change \(7.91/3.25^\circ\) to component form. Set right index of S on 7.91 of D. Move indicator to 3.25 on ST. Read 0.448 on D. To determine the decimal point, observe that the angle is small, and hence the \(y\) component will also be small. Obviously, when the hypotenuse is near 8, 0.448 would be too large, and 0.0448 too small, to produce an angle of 3.25°. The cosine cannot be set on ST, but the angle is so small that the \(x\) component is practically equal to the radius or hypotenuse. Hence 7.90 is a close approximation, and \(7.91/3.25^\circ = 7.90 + j0.448\).

(d) Convert \(263/160^\circ\) to the \(x + jy\) form. Since \(160^\circ > 90^\circ\), compute \(180^\circ - 160^\circ = 20^\circ\). Set left index of the S scale on 263 of D. Move indicator to 20 on S. Read 90.0 on D. Move the slide so that the right index of S is on 263 of D. Move indicator to 20 (reading from right to left) on S. Read 247 on D. Since the angle is in the second quadrant, \(263/160^\circ = -247 + j90\).

**ILLUSTRATIVE APPLIED PROBLEMS**

1. Two forces of magnitude 28 units and 39 units act on the same body but at right angles to each other. Find the magnitude and angle of the resultant force.

In complex number notation, the resultant is \(39 + j28\). Change this to exponential form. Since 28 < 39, then \(\theta < 45^\circ\). Set the right index of S on 39 of D. Move indicator to 28 of D. Read \(\theta = 35.6^\circ\) on T. Move slide so 35.6° on S is under the hairline. Read \(\rho = 48.0\) on D under the S-index. Hence the resultant has magnitude 48 units, and acts in a direction 35.6° from the larger force and 90°-35.6° or 54.4° from the smaller force. This angle can be read on the S scale under the hairline.

2. A certain alternating generator has three windings on its armature. In each winding the induced voltage is 266.4 volts effective. The windings are connected in such a way that the voltages in each are given by the following vector expressions.

\[
E_1 = 266.4 \cos 0^\circ - j \sin 0^\circ
\]

\[
E_2 = 266.4 \cos 120^\circ - j \sin 120^\circ
\]

\[
E_3 = 266.4 \cos 240^\circ - j \sin 240^\circ
\]

Express these numerically.

\[
E_1 = 266.4 (1 - j0) = 266.4 - j0
\]

To find \(E_2\), reduce the angles to first quadrant by taking \(180^\circ - 120^\circ = 60^\circ\). Set the right index of S on 266.4 of D. Move the indicator to 60 on S (reading right to left). Read 133.2 on D. Move indicator to 60 on S, read 230.7 on D. Then

\[
E_2 = -133.2 - j230.7
\]

To find \(E_3\), reduce \(240^\circ\) to the first quadrant by noting \(240^\circ = 180^\circ + 60^\circ\). Hence, except for a negative sign, \(E_3\) is the same as \(E_2\), and

\[
E_3 = -133.2 + j230.7
\]

Suppose the first and second windings are so connected that their voltages subtract; that is,

\[
E_0 = E_1 - E_2 = (266.4 - j0) - (-133.2 - j230.7) = 399.6 + j230.7
\]

This may be changed to the \(\rho/\theta\) form. Set the right index of S on 399.6 of D. Move the indicator to 230.7 of D. Read \(\theta = 30^\circ\) on T. Move slide so that \(30^\circ\) on S is under indicator, and read 461 on D at the S-index. Then \(E_0 = 461/30^\circ\), and hence the voltage is 461 volts and leads the voltage \(E_1\) by \(30^\circ\).
3. An alternating voltage of \(104 + j60\) is impressed on a circuit such that the resulting current is \(24 - j32\). Find the power and power factor. First convert each vector to exponential form.

\[
E = 104 + j60 = 120 \angle 30^\circ \text{ volts, approximately}
\]
\[
I = 24 - j32 = 40 \angle -53.1^\circ \text{ amperes, approximately}
\]

Hence the voltage leads the current by \(30^\circ - (-53.1^\circ) = 83.1^\circ\).

The power factor \(\cos 83.1^\circ = 0.120\).

The power \(P = EI \cos \theta = (120)(40)(0.120) = 576\) watts, approximately.

4. The "characteristic impedance" of a section of a certain type of line is given by the formula \(Z_0 = \sqrt{Z_3Z_4 + \frac{Z_2^2}{4}}\), where in each case, the symbol \(Z\) represents a vector quantity. Compute \(Z_0\) when

\[Z_1 = 40 + j120, \quad Z_2 = 220 - j110.\]

First convert to exponential form.

\[
Z_1 = 40 + j120 = 126 \angle 71.6^\circ
\]
\[
Z_2 = 220 - j110 = 246 \angle -26.6^\circ
\]

Hence

\[
Z_0 = \sqrt{(126)(246) \angle 71.6^\circ - 26.6^\circ} = \sqrt{31,000 \angle 45.0^\circ}
\]

\[
Z_0 = \sqrt{126^2 + \frac{246^2}{4}} = \sqrt{15,900 \angle 143.2^\circ}
\]

\[
Z_0 = \sqrt{3,975 \angle 143.2^\circ}.
\]

Since vectors are to be added before the square root is found, it is now convenient to convert them to component form.

\[
31,000 \angle 45.0^\circ = 21,900 + j21,900
\]
\[
3,975 \angle 143^\circ = -3,180 + j2,300
\]

To compute the latter, take \(180^\circ - 143^\circ = 37^\circ\), and observe that the \(x\) or real component must be negative since \(143^\circ\) is an angle in the second quadrant. Then

\[
Z = \sqrt{(21,900 - 3180) + j(21,900 + 2390)}
\]

\[
= \sqrt{18,720 + j24,200}
\]

In order to find the square root, it is convenient to change back to exponential form.

\[
Z = \sqrt{18,720 + j24,200} = \sqrt{30,600 \angle 52.4^\circ}
\]

\[
= 175 \angle 26.2^\circ \text{ ohms}.
\]

Note that the index marks (1) correspond with the index marks on the C, D, CF, and DF scales on the face of the rule.

Note the conversion mark 1 liter = 1 qt. on the slider. This mark is located for an exact conversion from liters to quarts and vice versa. Actually 1 liter = 1.05671 quarts and the conversion mark is located to that accuracy. Since the equivalent shown (1 liter = 1 qt.) is only used for decimal point location the exact equivalent does not appear on the rule. This is also true of the other conversion designations.

**Examples:**

1. Convert 12 inches to centimeters.

   Move the left index mark on the slide under the inch-cm. conversion mark on the top stator bar. Turn rule over and opposite 12 on C or CF read 30.5 centimeters on D or DF. Note that if 40 inches is to be converted to centimeters, that the CF and DF scales must be used, and if 15 inches is to be converted to centimeters, the C and D scales must be used. Any conversion can be made without resetting by using either the CF, DF or C and D scales.
2. Convert 30 centimeters to inches.
Move the left index mark on the slide under the inch-cm. conversion mark on the top stator bar. Turn rule over and opposite 30 on D or DF read 11.8 inches on C or CF. Note that if 20 centimeters is to be converted to inches, the DF and CF scales must be used and if 40 centimeters is to be converted to inches, the C and D scales must be used. Any conversion can be made without resetting by using either the CF, DF, or C and D scales.

Note that the settings for inches to centimeters or centimeters to inches are exactly reversed. This leads to the following rule:

If the conversion mark is on the top or bottom stator bar, set or read the first (the unit)* factor on the C or CF scale and the second factor on the D or DF scale.

*A The first or unit factor refers to the order of designation at the conversion mark. For example, 1 in. = 2.5 cm., inches is therefore the first or unit factor.

3. Convert 5 barrels to gallons.
Move the conversion mark for bbl. to gallons (on the slide) under the left index mark. Turn the rule over and opposite 5 on DF read 157.5 gallons on CF. Note that 5 cannot be set on D for this conversion since the C scale is not opposite D for this value.

4. Convert 5 gallons to barrels.
Move the conversion mark for barrels to gallons (on the slide) under the left index mark. Turn the rule over and opposite 5 on C read 1.388 barrels on D. Note that 5 cannot be set on CF for this conversion.

Note that the settings for barrels to gallons or gallons to barrels are exactly reversed. This leads to the following rule:

If the conversion mark is on the slide, set or read the first (the unit)** factor on the D or DF scale and the second factor on the C or CF scale.

Observing the rules above, work the following examples:

**PROBLEMS**

1. 12 nautical miles =x statute miles
2. 15 inches =x centimeters
3. 5 kilometers=x statute miles
4. 52 liters=x pounds water
5. 5 gallons=x cubic inches
6. 8 gallons=x pounds water
7. 6 bushels=x cubic feet
8. 55 M. P. H. =x ft. per second
9. 83 sq. miles=x acres
10. 75 pounds per sq. in. =x ft. water
11. 18 H. P. =x ft. pounds/min.
12. 96 BTU=x ft. pounds

**ANSWERS**

1. 13.82 mi.
2. 38.1 cm.
3. 3.11 mi.
4. 70.4 #H₂O
5. 693 in²
6. 66.7 #H₂O
7. 7.4 ft³
8. 80.7 ft/sec
9. 27,500 acres
10. 173.3 H₂O (PSI)
11. 594,000 ft. #/Min.
12. 74,700 ft. #

**HINTS**

*The first or unit factor refers to the order of designation at the conversion mark. For example, 1 bbl. = 52 gal., barrels is therefore the first or unit factor.

**HOW TO ADJUST YOUR SLIDE RULE**

A perfect slide rule, when out of adjustment, often appears defective. Each rule is accurately adjusted before it leaves the factory. However, during shipment, it may loosen the adjusting screws and throw the rule out of alignment. Follow these simple directions for slide rule adjustment.

**CUSTOM-HAIRLINE ADJUSTMENT**
Loosen the bottom two screws on both Cursor windows on spacer opposite tension spring. Press with left thumb to maintain constant contact with edge of rule, then adjust hairline on left hand index and tighten screws on this side. Turn rule over and check alignment of hairline on other Cursor window. If necessary, loosen all screws on this side and align with left hand indices as needed, and tighten screws carefully.

**SLIDER TENSION ADJUSTMENT**
Loosen slide rule screws on end brackets; regulate tension of slider, tighten the screws using care not to misalign the scales. The adjustment needed may be a fraction of a thousandth of an inch, and several trials may be necessary to get perfect slide rule action.

**SCALE LINE-UP ADJUSTMENTS**
(1) Move slider until indices of C and D scales coincide. (2) Move cursor to one end. (3) Place rule on flat surface with face uppermost. (4) Loosen end plate adjusting screw slightly. (5) Adjust upper portion of rule until graduations on DF scale coincide with corresponding graduations on CF scale. (6) Tighten screws in end plates.

**REPLACEABLE ADJUSTING SCREWS**
All Pickett All-Metal rules are equipped with Telescopic Adjusting Screws. In adjusting your rule, if you should strip the threads on one of the Adjusting Screws, simply "push out" the female portion of the screw and replace with a new screw obtainable from your dealer, or from the factory. We do not recommend replacing only the male or female portion of the screw.

**HOW TO KEEP YOUR SLIDE RULE IN CONDITION**

Always hold your rule between thumb and forefinger at the ends of the rule. This will insure free, smooth movement of the slider. Holding rule at center tends to bind the slider.

**LUBRICATION**
Your slide rule is treated with a light lubricant at the factory. This lubricant works into the surface of the metal, is designed to lubricate your rule indefinitely. If your rule should run dry, or if the slider begins to move hard or with a dry rasping sound:
1. Lubricate with a light lubricant.
2. Work in well by moving slider back and forth, then wipe off.
3. Any pure light oil is a satisfactory lubricant.

**MAINTENANCE**
The body of your rule is made of a corrosion resistant alloy. The edges may gradually darken (or oxidize) with age.
This normal aging of the rule affects neither the accuracy of the scales nor ease of operation.
Extreme atmospheric exposure tends to warp and distort wood, and to rust steel, which is common knowledge. This is not true of the alloy used in your slide rule, but, such exposure may tend to deposit an oxidation film on the surface, causing the slider to move harder.

If this happens to your rule, take out the Telescopic Adjusting Screws and remove both Top Rule Member and Slider without disassembling the rule. Clean the oxidized edges of the rule with a silver polish, Bon Ami, rubber ink eraser or other cleaning agent. Slide Top Rule Member and Slider back into position. Re lubricate. Then make Sure Line-Up and Slider-Tension Adjustments.

**WHY YOUR RULE OPERATES BETTER WITH CONSTANT USE**
Being made of metal, the moving parts of your slide rule "lap in" with use. This process of wearing smooth means your slide rule will operate with increasing smoothness year after year.

**CLEANING**
Wash surface of the rule with non-abrasive soap and water when cleaning the scales. If Cursor window becomes dulled from long use, simply polish and brighten the window surfaces with a small rag and tooth powder.
